

Dénivelé positif du parcours cycliste de l'Embrunman

Pourquoi 5000 m ?

Sommaire :

*(la pagination est celle du fichier informatique *.pdf et non celle du document papier)*

Préambule	p 2
Note du service après-vente de POLAR	p 4
Données brutes d'un fichier d'enregistrement POLAR S710 avec un échantillonnage de 5 secondes	p 6
Graphe présentant le profil du parcours avec les données issues du fichier de données brutes (échantillonnage de 5s)	p 74
Données du fichier brut ramenées à un échantillonnage de 15 secondes	p 75
Graphe présentant le profil du parcours avec les données échantillonnées toutes les 15 secondes	p 109

Préambule :

Depuis 2 ans l'annonce d'un dénivelé positif du parcours cycliste de l'Embrunman proche de 5000 m a suscité quelques réactions.

Plusieurs raisons peuvent être invoquées.

Première raison possible de la contestation : le décalage annoncé par POLAR, entre le résultat annoncé par le logiciel et par la montre (mesure dite « en temps réel ») et les données brutes contenues dans la montre et relatives au choix préalable de l'échantillonnage.

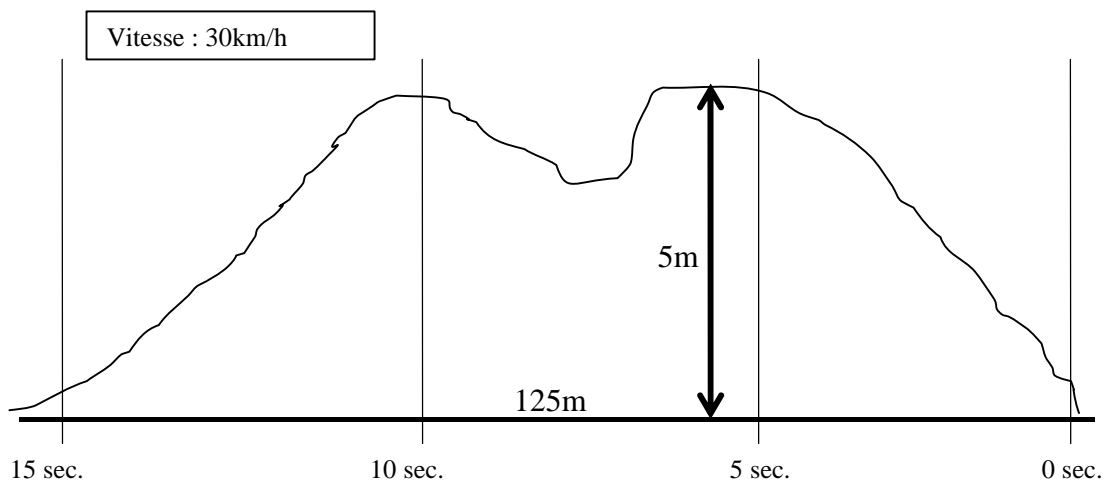

C'est selon ces dernières données brutes, en les transposant sur une feuille Excel, que j'ai calculé le dénivelé positif : j'ai sommé tous les dénivelés positifs calculés entre deux mesures successives (définition fondamentale d'un dénivelé positif !).

On remarquera que les autres sources d'erreurs annoncées par POLAR et évoquées par certains contestataires sont de fait prises en compte dans ces calculs. Par exemple l'altitude du Col d'Izoard qui est officiellement de 2362m a été mesuré lors de cet entraînement à 2346m sur une montre étalonnée dès le départ à 816m. Par contre l'altitude d'arrivée n'est plus de 816m mais de 845. L'un dans l'autre, ce qui est perdu en haut est sans doute récupéré à la fin avec il est vrai, mais cela reste à démontrer sur l'ensemble de l'entraînement, une légère majoration.

Autre raison (mais c'est finalement un corollaire !) : les personnes qui contestent ce résultat argumentent en avançant que **lors de l'épreuve** de l'EmbrunMan leurs enregistrements donnent une valeur comprise entre 3600m et 3800m. C'est un fait indéniable si l'échantillonnage choisi est de 15 secondes, or pour enregistrer l'épreuve dans son intégralité avec un POLAR S710 on est obligé de choisir cet échantillonnage de 15s, vu que qu'avec un échantillonnage de 5s il n'y a que 8h56 de capacité de stockage dans la montre.

Le résultat de 5000m (4992 « exactement » : mais peut-on être aussi précis ?) a été mesuré avec un échantillonnage de 5 secondes **lors d'une reconnaissance du parcours seule**, ce qui multiplie environ par 3 le nombre de données (5000 données pour « 5s », contre 1700 pour « 15s ») et accroît ainsi la précision de la mesure. Et pour ceux qui en douteraient, il suffit de lire la note de POLAR joint à cette étude pour s'en convaincre. Cela étant c'est du bon sens : en enregistrant l'altitude toutes les 5s on prend en compte plus de petites de petites bosses qu'en l'enregistrant toutes les 15s.

Illustration (voir dessin ci-dessous) : pour une vitesse supposée constante de 30km/h la montre prendra 2 altitudes identiques avec un échantillonnage toutes les 15s (ascension nulle), alors qu'avec un échantillonnage de 5s la montre enregistrera 4 altitudes donnant une ascension de +5m.

Pour mettre en évidence la différence entre les 2 modes de recueil de données (échantillonnage de 5s et de 15s) j'ai supprimé au fichier « 5s » deux lignes sur trois de sorte que je me suis retrouvé avec un fichier de données échantillonnées toutes les 15s. J'ai ensuite comparé les dénivelés positifs calculés à partir de chacun de deux fichiers (méthode annoncée au début de ce texte). Et le fichier échantillonné toutes les 15s donne ainsi un dénivelé positif de 3883 m contre 4992 m pour le fichier échantillonné toutes les 5s. Pourtant cela n'enlève rien au profil de la course comme en atteste les deux graphiques correspondants.

J'ai effectué la même démarche avec un fichier enregistré dans un col d'une dizaine de kilomètres et ne présentant strictement aucune descente aussi petite soit-elle. Dans ce cas les dénivelés obtenus en configuration « 5s » et « 15s » sont identiques.

Ainsi on peut dire (mais les connaisseurs de l'Embrunman le savent bien) que s'il y a une telle différence dans la mesure du dénivelé positif entre le fichier « 5s » et le fichier « 15s » pour le parcours cycliste de l'Embrunman, c'est que, en dehors des difficultés classiques (montée des Puys, Izoard, Côte Pallon, Chalvet), les successions de petites côtes et de petites descentes sont très nombreuses lui conférant des vertus « cassantes » pour nos petites guibolles !!!

Quoiqu'il en soit chers « Embrunmanophiles », ce Triathlon reste ce qu'il est, dur, magnifique, transcendant, et nos considérations météorologiques ne doivent pas lui porter atteinte.

Bon entraînement, et rendez-vous chez Coco pour une mousse !!!

cyrilgautier@wanadoo.fr

INFORMATIONS SUR LES DONNES ALTITUDE ET MONTEE

L'altitude est mesurée à partir de la pression atmosphérique avec la sonde de pression embarquée dans le récepteur Polar.

Les conditions atmosphériques causent une certaine erreur dans les mesures. Par exemple, quand l'altitude d'un point de départ est enregistré dans le récepteur et que l'on vérifie ce même point plusieurs heures après, la valeur peut dériver de plusieurs mètres suivant les conditions climatiques. Par conséquent, la mesure d'altitude faite par la sonde de pression ne peut pas calculer la valeur absolue d'altitude, mais seulement la différence d'altitude pendant l'exercice.

Des erreurs internes peuvent également affecter la mesure d'altitude :

La sonde de pression possède quelques non linéarités normales, qui causent des erreurs dans la mesure de pression et par conséquent dans la mesure d'altitude.

La sonde de pression qui est utilisé dans les récepteurs Polar (et également dans les produits concurrents) est sensible aux changements de température. Par conséquent, la sonde de pression est compensée en température à l'usine de fabrication, mais néanmoins des erreurs subsistent.

La valeur qui est mesurée avec la sonde de pression est convertie en valeur numérique, cad numérisé. L'altitude est calculée à partir de cette valeur en utilisant la norme ISO2533. Le calcul contient quelques inexacitudes dues à la numérisation, qui entraîne par conséquent des erreurs de calcul.

En définitive, il y a 4 sources principales d'erreur :

1. *Erreur 1 : La non linéarité de la sonde de pression*
2. *Erreur 2 : L'influence de la température sur la sonde de pression*
3. *Erreur 3 : Le calcul de l'altitude.*
4. *Erreur 4 : Les conditions climatiques.*

Ces erreurs affectent à la fois les valeurs d'altitude et de montée sur le récepteur.

Erreur 1 et 3

La somme des erreurs 1 et 3 pendant la mesure peut être de +/- 2% maximum.

Cependant l'erreur typique se situe à +/- 1 %. Données à une température constante de + 25 degrés.

Erreur 2

L'erreur 2 est calculée dans une gamme de température allant de -10 à +60 degrés. L'erreur basée sur la température dépend de l'altitude. Sur la gamme de température, l'erreur, à une altitude au niveau de la mer, est d'environ +/- 8m. A 1000m, l'erreur est de +/- 9m, à 3000m elle est de +/- 12m, et à 7000m, elle est de +/- 17m. Cependant, aux altitudes élevées les écarts de température sont normalement plus petits et, donc l'erreur basée sur la température est également plus petite.

Erreur 4

L'erreur 4 dépend du temps, cad suivant la pression atmosphérique. L'erreur varie suivant un temps pluvieux (basse pression) et un temps ensoleillé (haute pression).

Exemple d'erreur :

Point de départ : 300m Point d'arrivée : 800m Valeur enregistrée dans le récepteur : 300m

L'erreur maximale de la valeur d'altitude est la suivante :

Erreur 1 et 3 : La différence d'altitude est de 500m (800m – 300m), donc l'erreur maximum est +/-10m (+/-2% de 500m)

Erreur 2 : L'erreur basée sur la température est environ de +/-9m (à 500m)

L'erreur maximale (somme des erreurs) – en supposant que les conditions atmosphériques sont stables – est de +/- 19m

Si les conditions atmosphériques n'ont pas changé, la valeur mesurée au point final (800m) ,peut être entre 781m et 819m.

Cependant les conditions atmosphériques (Erreur 4) change, l'erreur d'altitude peut être plus importante.

En outre, des différences entre les données du récepteur (File) et les données transférés sur ordinateur peuvent être légèrement différente. La cause de cette différence est due à l'échantillonnage d'enregistrement des données. Le récepteur enregistre les données automatiquement en temps réel alors que les données pour le

transfert sur ordinateur sont enregistrées suivant la fréquence d'enregistrement programmée dans le récepteur (Rec rate : 5s, 15s ou 60s). Afin de diminuer l'erreur liée à la fréquence d'enregistrement, il est recommandé de programmer une fréquence à 5s.

Salutations sportives.

Profil du parcours cycliste d'Embrun établi sur la base des données d'un fichier Polar S710 avec un **échantillonnage de 5s**

Altitude m

	A	B	C	D	E
1	<p>Les données ci-dessous sont extraits du même fichier queLes colonnes en rose contiennent les données brutes d'un Polar™ S710 obtenues par <u>un échantillonnage de 5 secondes mais dont les seules les données enregistrées toutes les 15s ont été conservées</u>. En effet afin de comparer les résultats obtenus par beaucoup d'athlètes sur le triathlon d'Embrun lui-même (échantillonnage de 15 secondes) j'ai supprimé 2 données consécutives par 15 secondes.</p> <p>Le résultat est en bas (ligne 1686) : c'est la somme de tous les dénivelés positifs pour 15 sec.</p>
